6.2.3 Community Results Discussion: Gjoa Haven

The survey frame:

An assessment of under-enumeration during the community visit revealed that there were approximately 22 hunters who were not registered in the Harvest Study. Eighteen of these were Inuit – all were occasional hunters. It is estimated that there were four non-Inuit hunters with assigned hunting rights who were not registered, also all occasional hunters. As discussed in Section 5.2.1 the effect of this under-enumeration would have led to a downward bias of the harvest estimates. However, the extent of the bias is likely very small since the missing hunters are all occasional hunters and only represent six percent of the total hunter population (Table 10).

Due to the relatively small number of intensive hunters registered in Gjoa Haven, the intensive classification was joined with the active classification for the purpose of calculating harvest estimates.

The HTO Board felt that there were more than eight intensive hunters in the community. Given that all the un-registered hunters identified were occasional hunters it is likely that some intensive hunters were misclassified rather than un-registered. The effect of this should be minimal since, as discussed above, we have joined the active and intensive classifications for the estimate calculations.

Survey coverage and non-response bias:

Response rates although good in most months, were lower in the first few months of the study and in the summer and fall of 1998 (year 3), with five months below 75%. As seen in Table 9 the consistent intentional non-response rate in Gjoa Haven was low, at 0.4%, and was not thought to be a potential source of non-response bias.

Response rates were felt to be high enough and non-response bias low enough during most years to ensure that n did in fact constitute a sufficiently representative sample of N hunters. Readers should exercise caution when using the data collected during the summer and fall of years 1 and 3 of the study since the potential for both sampling error and non-response bias increases as response rates fall.

Measurement issues and response error:

During the community visit it was reported that in following Inuit tradition, hunters do not reveal exact counts of harvests – since it is against tradition to count and report their harvest. It was suggested that some hunters may have underestimated and under-reported their harvest, especially for some species such as birds and small game. Readers should also refer to Section 5.4 for a thorough discussion of this issue.

As seen in the recall period tables, the vast majority of the harvest records in years 1, 4 and 5 were collected within three months of the harvest. In years 2 and 3 there were several months with longer recall periods, however most were still under six months. The ability of a hunter to remember their harvest would tend to decrease as the recall period lengthens suggesting that some measurement error may have occurred where recall periods were longer.

As noted in the comments associated with arctic char, below, there was some commercial harvesting of arctic char during the study. It is thought that some of this commercial harvest may have been reported with the subsistence harvest.

Community feedback and other sources of data:

1. **Caribou:** Caribou harvesting consisted almost entirely of barren-ground caribou, however some island caribou and even a few Peary caribou were reported during the study. For the purpose of calculating harvest estimates they were combined into one category.
2. **Musk-ox:** Harvest estimates seem low (C.F.). DSD reports the following harvest numbers for musk-ox (DSD MXc):

Year 1	Year 2	Year 3	Year 4	Year 5
n/d	34	n/d	n/d	30

   The above data provided by DSD did not specify whether the hunts were subsistence or sport hunts, however we were informed that there are usually 3 to 5 sport hunts per year. This would indicate that the subsistence harvest for years 2 and 5 should be at least 29 and 25 respectively. These data indicate that harvest estimates in years 2 and 5 appear to be low.
3. **Polar bear:** Numbers displayed are not estimates but confirmed harvest numbers supplied by DSD (DSD PB).
4. **Wolf:** Harvest estimates seem a little low (C.F.). Data were obtained from DSD detailing the number of pelts sold by hunters. DSD reports were available for 1999/2000 and 2000/2001 (years 4 and 5) and indicate that 6 wolf pelts were purchased in 1999/2000 (year 4) and 5 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). Based on this information the harvest estimate for year 5 does appear low however the estimate for year 4 looks to be in the right range.

[5] **Arctic fox:** Harvest estimates in years 3 and 5 seem too low (C.F.). Again DSD reports were consulted and they showed that 6 pelts were purchased from Gjoa Haven hunters in 1999/2000 (year 4) and 54 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). Given the harvest estimates shown it appears that the estimate in year 5 is low.

[6] **Wolverine:** Harvest estimates seem low (C.F.). DSD reports were consulted but did not show any records of pelts purchased in years 4 or 5 (DSD FB).

[7] **Small game:** Hunters indicated that many were not reporting small game harvests to the Fieldworker so estimates seem very low. Many hunters did not think to report these species (C.F.).

[8] **Bearded seal:** In years where 0 were recorded there were likely some caught but not reported (C.F.).

[9] **Geese:** Harvest estimates for snow geese seem accurate. CWS supported hunts in years 4 and 5 resulting in more harvesting during these years. However, estimates for all other waterfowl seem low (C.F.).

[10] **Ptarmigan:** Harvest estimates seem low. Hunters reported that they were not specifically asked how many animals they harvested of each species. They were only asked what they caught. Many hunters did not think to report their small game and bird harvests (C.F.).

[11] **Eggs:** Again, harvest estimates appear low. Large numbers of eggs are gathered each year but again many hunters did not report them to the Fieldworker (C.F.).

[12] **Arctic char:** Harvest estimates seem to be in the right range (C.F.). Hunters reported that there was some commercial fishing early in the study and some may have been reported. There were no records in the database which indicated that the catch was commercial, however some commercial catches may have been reported. DFO records confirm that there was commercial fishing of arctic char during the study (DFO F).

[13] **Lake trout:** The year 1 harvest estimate seems low since there are many trout caught each year in the spring. Estimates in the other years look accurate (C.F.).

[14] **Least cisco:** Harvest estimates seem too low; some are taken every year. It was reported that most people did not record these fish. They are caught in nets and when checking nets there can easily be 50 in one day alone (C.F.).

Although no beluga whales were reported to the Harvest Study Fieldworker, DFO records show a harvest of 3 animals in 1999/2000 (DFO N/B).
