6.2.4

6.2.4 Community Results Discussion: Kugaaruk

The survey frame:

An assessment of under-enumeration during the community visit revealed that there were approximately 68 hunters who were not registered in the Harvest Study. Sixty-seven of these were Inuit - 62 occasional and five active hunters. It is estimated that there was one non-Inuit hunter with assigned hunting rights who was not registered – an occasional hunter. As discussed in Section 5.2.1 the effect of this under-enumeration would have led to a downward bias of the harvest estimates. Given that these unregistered hunters represent forty percent of the total hunter population and that five of the hunters were active hunters (Table 10) the effect of this bias on harvest estimates is likely very significant and could have caused an under-estimation of the community harvest of up to 50%. Harvest estimates for the unregistered hunters can be estimated using mean harvest quantities for each species by strata. However, these estimates, having their own sources of error and bias, are beyond the scope of this Final Report. Readers may apply to NWMB to obtain the results of these calculations.

Survey coverage and non-response bias:

Response rates although good in most months, were lower in year 1, when rates dropped below 50% in a few months, and in the first month of year 2. In years 3 to 5 response rates were high in almost all months, with only the occasional month below 75%. As seen in Table 9 the consistent intentional non-response rate in Kugaaruk was nil, and therefore was not a potential source of non-response bias.

Response rates were felt to be high enough and non-response bias low enough during years 2 to 5, with the exception of the first month in year 2, to ensure that n did in fact constitute a sufficiently representative sample of N hunters. Readers should exercise caution when using the data collected during year 1 and during the first month of year 2 (June 1997) since the potential for both sampling error and non-response bias increases as response rates fall.

Measurement issues and response error:

It was reported during the community consultations that some egg harvests were under-reported. Further details are provided in the community feedback and other sources of data section below. Section 5.4 also contains a thorough discussion of this issue.

As seen in the recall period tables, years 1, 2 and most of year 5 had short recall periods with the majority of harvest records having been collected within three months of the harvest, minimizing measurement error due to recall failure. However, recall periods were much longer, over six months in many cases, during several months in years 3 and 4. Recall error in these instances is more likely.

As noted in the comments associated with arctic char, below, there was commercial harvesting of char during the study. It appears that harvest estimates do include some of the commercial harvest early in the study and should be considered too high if only considering the subsistence harvest of the community. However, in the latter years of the study harvest estimates are thought to be too low to include both subsistence and commercial harvests.

Community feedback and other sources of data:

1. **Caribou:** Caribou harvesting consisted of both barren-ground caribou and island caribou. Also, some hunters did not specify the type of caribou harvested. For the purpose of calculating harvest estimates they were combined into one category. All harvest estimates appear too low (C.F.).
2. **Musk-ox:** The community was issued 15 tags per year but not all were taken. The HTO Board estimates about 5 per year were used. Although the year 2 estimate seems too low, some others seem a little high. The annual mean appears to be in the right range (C.F.).
3. **Polar bear:** Numbers displayed are not estimates but confirmed harvest numbers supplied by DSD (DSD PB).
4. **Tundra grizzly:** The community generally harvests about 1 bear annually, so data from years with no reported harvest may be incorrect (C.F.).

[5] **Wolf:** Harvest estimates seem a little low. Data were obtained from DSD detailing the number of pelts sold by hunters. DSD reports were available for 1999/2000 and 2000/2001 (years 4 and 5) and indicate that 40 wolf pelts were purchased in 1999/2000 (year 4) and 27 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). Based on this information the harvest estimates do appear to be low in the last two years of the study.

[6] **Arctic fox:** Again, DSD provided reports for 1999/2000 and 2000/2001 (years 4 and 5) which indicated that 28 arctic fox pelts were purchased in 1999/2000 (year 4) and 48 were purchased in 2000/2001 (year 5) (note that DSD data are based on harvest years that run from July to June, whereas Harvest Study data are based on harvest years that run from June to May) (DSD FB). Based on this information the harvest estimates may also be somewhat low.

[7] **Seals:** Most of the unidentified seals were likely ringed seals. Harvest estimates may be a little low in some years but are in the right range. However, hunters reported that harbour seals are not hunted by the community and they questioned the report of this harvest in year 4 (C.F).

[8] **Narwhal:** Some of the harvest estimates seem too low (C.F). The community had an annual quota of 10 but had harvested over quota on some occasions. However, there was one year in which no narwhal were harvested, so the data indicating no narwhal harvests in year 4 is accurate. DFO reports the following harvest numbers for narwhal (note that DFO data are based on fiscal years, whereas Harvest Study data are based on harvest years that run from June to May) (DSD N/B):

96/97	97/98	98/99	99/00	00/01
7	15	8	0	30

These data indicate that harvest estimates appear low in four years of the study.

[9] **Snow goose:** Harvest estimates seem low. Approximately 15-20 snow geese are harvested every year (C.F.).

[10] **Canada goose:** As per the snow goose comments above, about 15-20 Canada geese are harvested annually (C.F.).

[11] **Eider duck:** Both king and common eiders are harvested around the community, however neither are very abundant (C.F.).

[12] **Eggs:** Harvest estimates appear too low. Hunters commented that they did not know to report eggs. Eggs are harvested every year; mostly seagull eggs but some goose and eider duck eggs are also gathered (C.F.).

[13] **Arctic char:** Harvest estimates in years 4 and 5 seem too low. Arctic char were fished commercially in about 12 places around the community. It appears that in years 1 and 2 some of these commercially caught fish were reported, whereas estimates in the later years are thought to be too low and not to include commercial fishing (C.F.). DFO records confirm that commercial quotas were issued during each year of the study (DFO F).

[14] **Lake trout:** The HTO Board estimates that the community harvests between 600 and 700 annually. Based on this information estimates in some years may be low (C.F.).

[15] **Sculpin:** The estimate in year 2 seems high, but harvesters often catch them in nets when fishing for other species – they are usually thrown back in the water though (C.F.).
